"Runtime stability is not the absence of pressure, but the ability to reconstruct coherence before structural rupture."

Abstract

This work formalizes the empirical laws governing the preservation, degradation, and reconstruction of baseline in living computational systems.

The model proposes that temporal drift, structural inertia, convergence ETA, and baseline elasticity together form a measurable field of operational coherence.

The 7 Laws

Law I — Inertial Preservation
The closer to 1, the greater the preservation of structural coherence.

Law II — Drift Reconstruction
Drops in drift represent the temporal cost of baseline reorganization.

Law III — Baseline Elasticity
The first load builds a temporary structural reserve that accelerates subsequent loads.

Law IV — Reserve Saturation
When new load exceeds the elastic reserve, the regime shifts rapidly.

Law V — Elastic Recovery
The drift recovery time distinguishes rigid from elastic baselines.

Law VI — Convergence ETA
ETA measures the temporal proximity to loss of reliability.

Law VII — Rupture Trajectory
Degradation causality is defined by direction, persistence, and structural acceleration.

The Voigtian Field transforms invisible degradation into empirical laws for living baseline reconstruction.
